

A Second Look at DEM's

Overview

Detailed topographic data is available for the U.S. from several sources and in several formats. Perhaps the most readily available and easy to use is the National Elevation Dataset. This dataset is built from the 7.5' 30m datasets that will be discussed later. The dataset may be viewed and selected portions downloaded from the [Seamless Data Website](http://seamless.usgs.gov/viewer.htm) (<http://seamless.usgs.gov/viewer.htm>) – a JAVA applet.

Navigate to the area of interest using the navigation tools () then delineate the area to be downloaded with the selection tools (). Once this is done, download processing will begin and you'll see a window similar to that below. Click Download by "NED" to save to your workstation in ArcGrid format..

The National Map Seamless Data Distribution System

SDDS Request Summary Page Help!

Your data request consists of **2 product(s)**, broken into **2 individual piece(s)**. The data will be delivered through an **on-line download interface**. The 'Modify Data Request' button will allow you to specify different formats, products, or media. Clicking on the name of the Product will allow you to order the entire dataset from pre-mastered originals using the EROS Data Center Order pages. You may bookmark this page to return to this data request and download the same pieces.

Data Extraction Request Pieces:

Product	Southwest (Bottom Left) Corner	Northeast (Top Right) Corner	Size (MB)	Link
NED - ArcGrid format	39.063329 N, 84.561971 W	39.187374 N, 84.381072 W	1	Download
NLCD 1992 - Land Cover - ArcGrid format	39.063329 N, 84.561971 W	39.187374 N, 84.381072 W	1	Download

This dataset is in a format that may be directly added to an ArcMap project.

Converting USGS DEMs (Digital Elevation Models) in SDTS (Spatial Data Transfer Standard) in ESRI grid files use to be extremely cumbersome in ArcView 3.x. With ArcGIS, however, the process is much simpler (although still not as easy as with Global Mapper).

The USGS no longer distributes DEMs on their website (<http://edc.usgs.gov/geodata/>) although they are still available from the state of Ohio (<ftp://ftp.geodata.gis.state.oh.us/geodata/dem/>). Although there are a variety of outlets where you can download these data (see above USGS link for URL's), I prefer GeoCommunity's website (<http://www.gisdatadepot.com/dem/demdownload.html>) which has the least advertising (there's still plenty). Registration is necessary to download data (and will sign you up for a daily GIS newsletter). You should already have an account with Geocommunity if you've done the first assignment.

Downloading Data from GeoCommunity

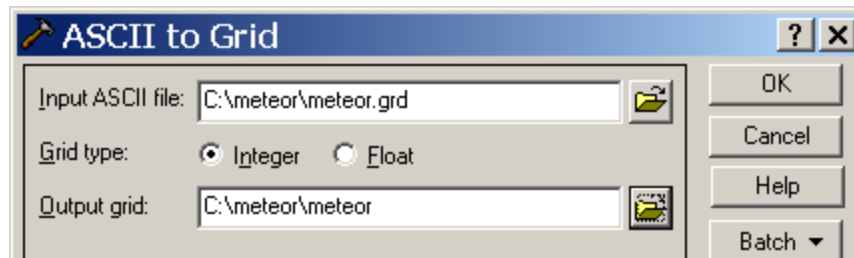

1. Go to the URL given above.
2. Click on the appropriate state, then county. Click *Digital Elevation Models (DEM)* - 2. Click the green (free) download arrow on the right side of the quadrangle you wish to download.
3. Click the save file button on the dialog box and use the browser that then appears to specify a storage location. I suggest placing the file in a folder labeled with the quads name because the file just has a numeric designation. Don't use non-DOS characters in the file name (such as space).
4. When the download is complete, unzip the file producing many smaller files (another reason to put each download in a separate folder).

Reading data with ArcToolbox

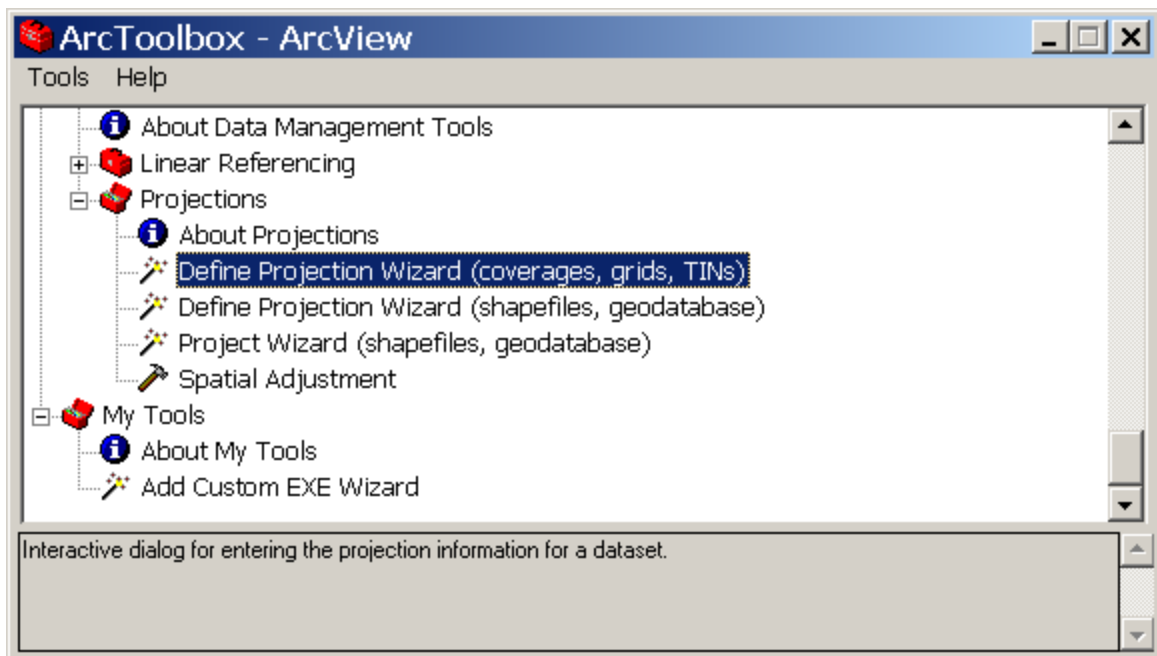

1. Start ArcToolbox from the ESRI ArcGIS folder on the start menu.
2. Open the *Import to Raster toolbox* (click on '+' sign) if it is not open already.
3. Double Click on *SDTS raster to grid* button which will bring up a browser in which you can navigate to the DEM folder you created above. Note that the folder must not be within any folder which has a space in its label.
4. Enter a name for the output grid.
5. When you click on the appropriate folder, an *open* dialog box should appear in which the numeric prefix of your DEM should appear in the right-hand panel. Double click on this prefix and your DEM will be converted an ESRI raster. Note that this process produces many files all of which are stored in a folder with the label you specified in step 4.

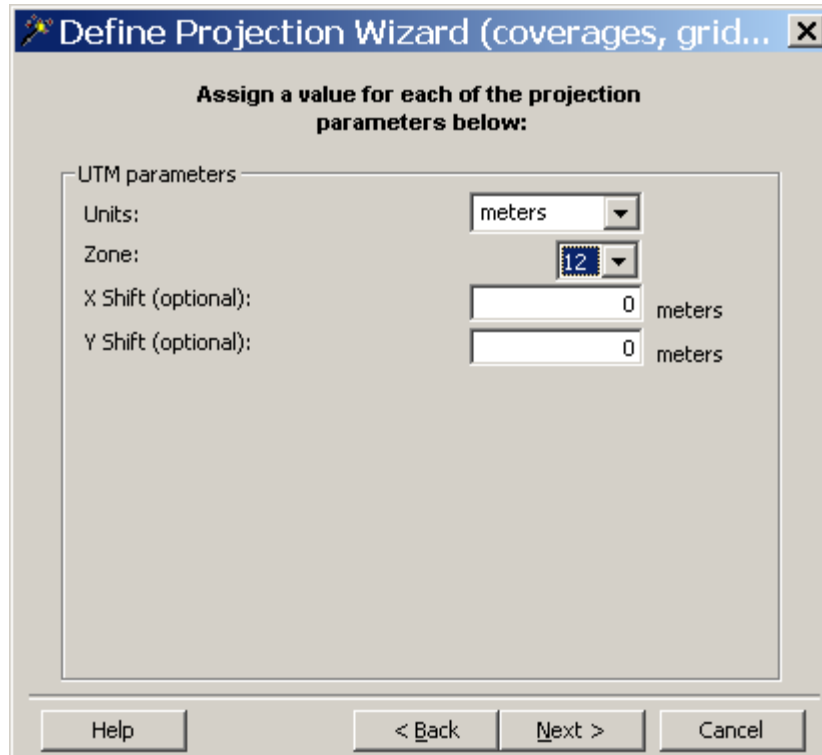

Reading data into Global Mapper

1. Double click on zipped file.
2. Export file or files (the fact that Global Mapper will mosaic datasets together is one of the many advantages of the program) to a raster file using the Arc ASCII format. It is important that you save this file in a location that does not have spaces in its path name because the ArcToolbox conversion program can't handle that.
3. Open Arc Toolbox and run "ASCII to Grid" from the "Input to Raster" tool set.

4. It's a good idea to define the projection of this newly created grid (you can read the projection information in Global Mapper) using Arc Toolbox. Select the "Define Projection Wizard (coverages, grids, TINs)" from the Projects box and follow the same procedure we used in class last week.

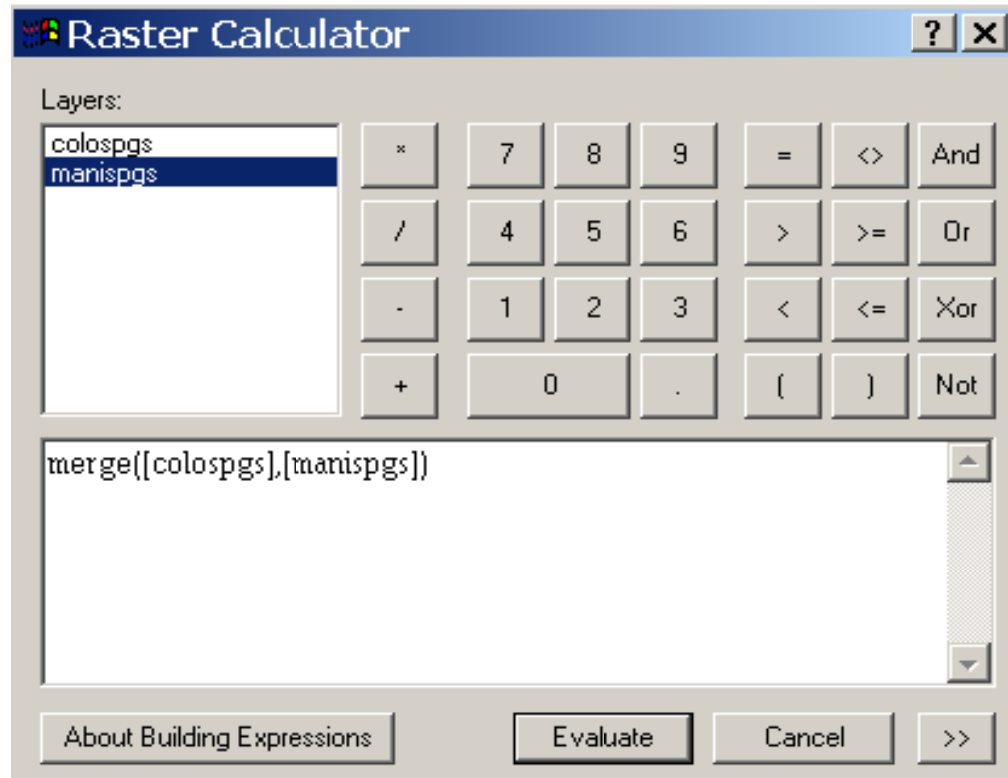

Opening Raster Dataset in ArcGIS

1. Start ArcMapper from the ESRI ArcGIS folder on the start menu.
2. Click on  to add your ESRI grid. Use the resulting browser to locate your grid and double click on it.
3. A dialog box will appear asking if you want to create pyramids. Click *OK* (Kelly LaBlanc disagrees and recommends declining for faster processing) A black and white image in which white corresponds to the highest and black to the lowest elevations will appear.
4. You can repeat the steps above to mosaic other quads but they will all have a different stretch function.

Mosaicing DEMs together in ArcMapper (if you didn't export from Global Mapper)

1. Pull down *Tools>Extensions* and make sure there's a check mark next to *Spatial Analyst*.
2. Pull down *View>Toolbars* and make sure that *Spatial Analyst* is selected.
3. On the spatial toolbar, click on the down arrow and select options.
4. Read the information on the *General* tab. You may want to change something but probably not. It's important to remember the location of the *working directory* it is using. Leave this dialog box open for the next step.

5. Click on the *Extent* tab and pull down *Analysis Extent* to *Union of inputs*. Close the dialog box
6. Pull down the arrow on the Spatial Analyst toolbar again, this time selecting Raster Calculator. This will bring up a dialog box that will look similar to the one below

7. In the lower dialog box type “**merge**” Leave dialog box open for next step.
8. Click on the name of the first quad to mosaic in the upper dialog box.
9. Type a “,” after the map name when it appears in the lower dialog box.
10. Repeat steps 8 and 9 until all of the maps have been added then type “)”.
11. Press the “*Evaluate*” button. The mosaic of the maps will be added to the currently opened project.
12. Double click on the mosaic’s name in the table of contents and select the Symbology tab. Click on *Stretched* in the panel on the left side of the symbology dialog box.

Producing a Shaded Relief Map from DEMs or DEM Mosaics with ArcMap

1. Open ArcMapper making certain that the Spatial Analyst extension has been selected and the Spatial Analyst toolbar is visible.

2. Pull down the arrow on the *Spatial Analyst* toolbar to *Surface Analysis* and select *Hillshade*.
3. Select the dataset from which you want to produce the shaded relief map and the name you want to give to the output data set (once again, remember that this name will be given to a folder containing many files). You may also wish to add some vertical exaggeration (*Z factor*) but don't get carried away. I suggest not touching the illumination *azimuth* and *altitude* unless you know what you're doing.
4. Click okay

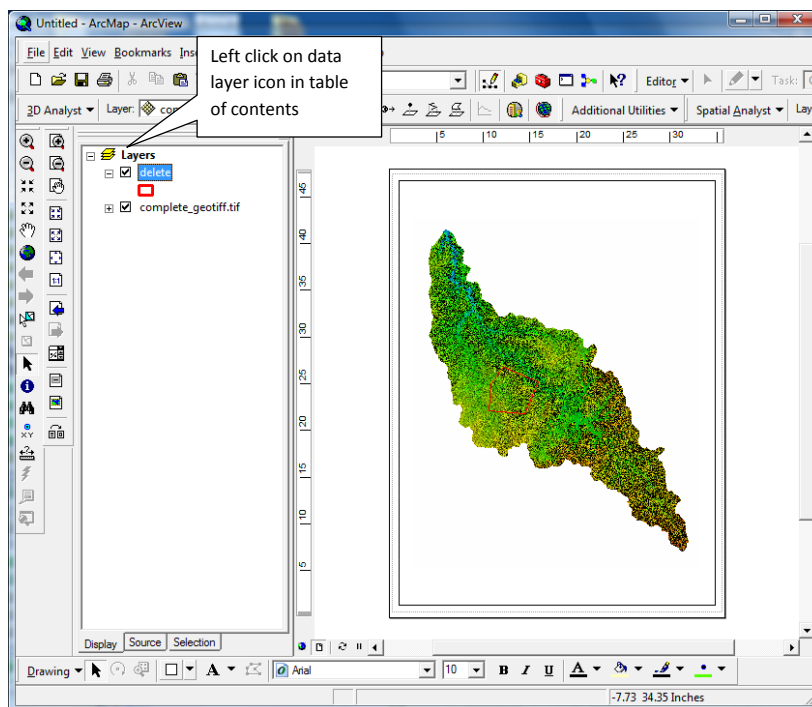

Clipping versus Using a Data frame with an ESRI Raster

Frequently it will be necessary or desirable to display only a portion of a raster's full extent (e.g., when you wish to only display that portion of a state DEM for a single county). There are several ways this can be done. One way is to clip the raster to produce a smaller subset of the full extent containing only the extent of the area of interest. The other way is to specify a frame that will only display that portion of the raster that is of interest. Both methods have their advantages and disadvantages.

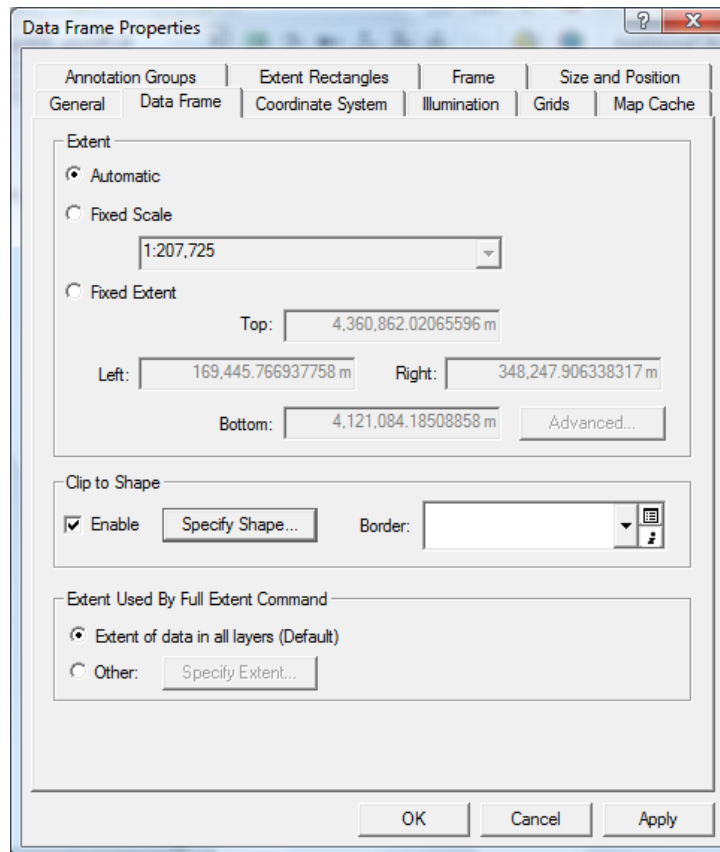

Using a Data frame with an ESRI Raster

To use a data frame to limit the display of a raster's full extent

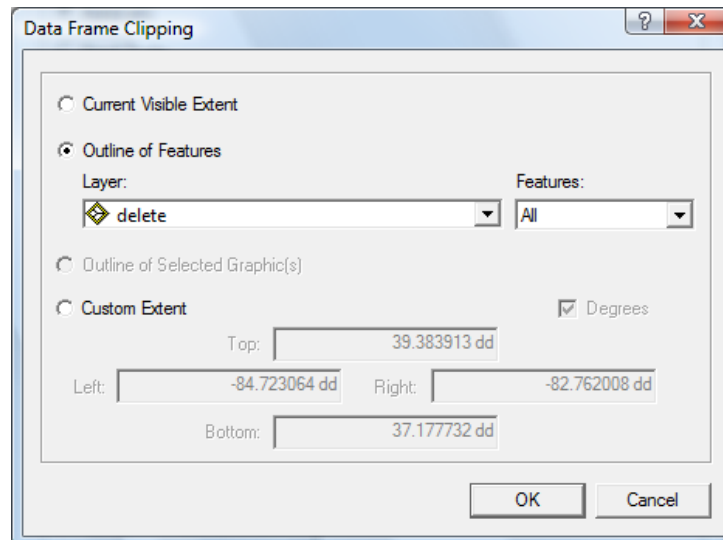

1. Start by left clicking on the data frame icon in the table of contents and select properties from the pull down.

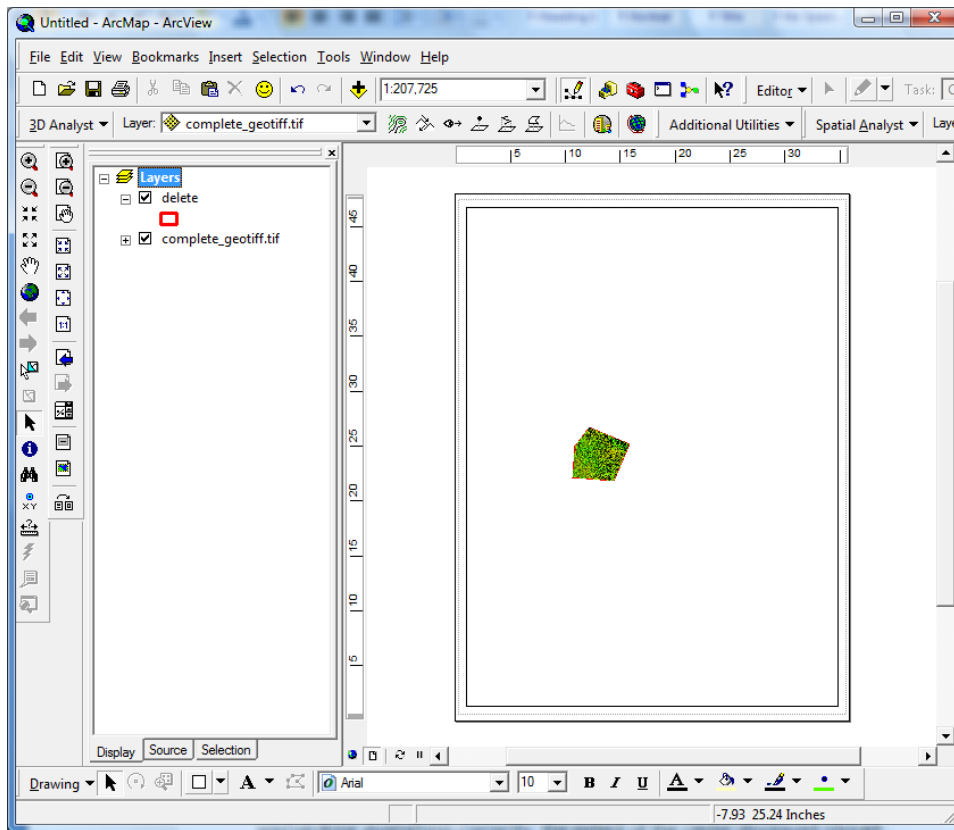

- In the resulting properties dialog, select the **Data Frame** tab and click on the check the **Click to Shape** check box.

- Click the **Specify Shape** button to bring up a dialog in which you select the feature to which you wish to limit the display of the raster's extent.
- In the resulting dialog, click the **Outline of Feature** radio button and select the framing feature.

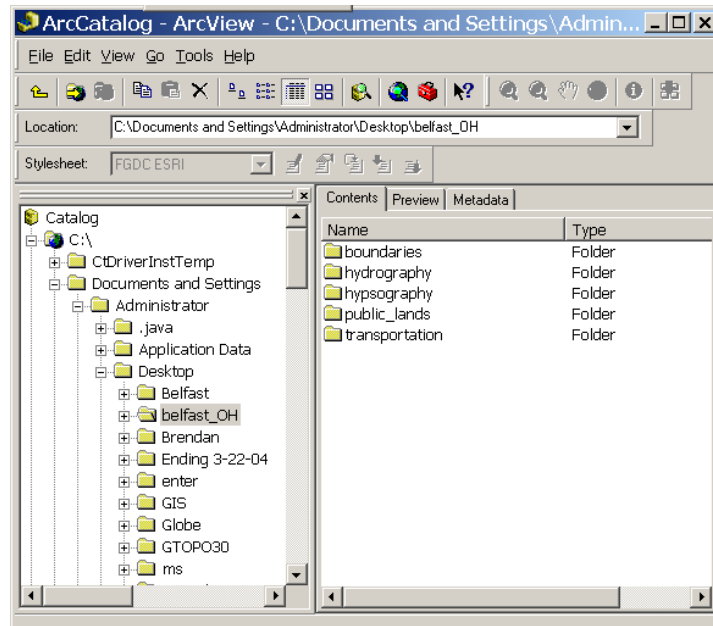

- Click **OKs** to back out of the dialogs and return to the ArcGIS window. If you've done everything correctly, the extent of the raster displayed should correspond to the extent of the masking feature.

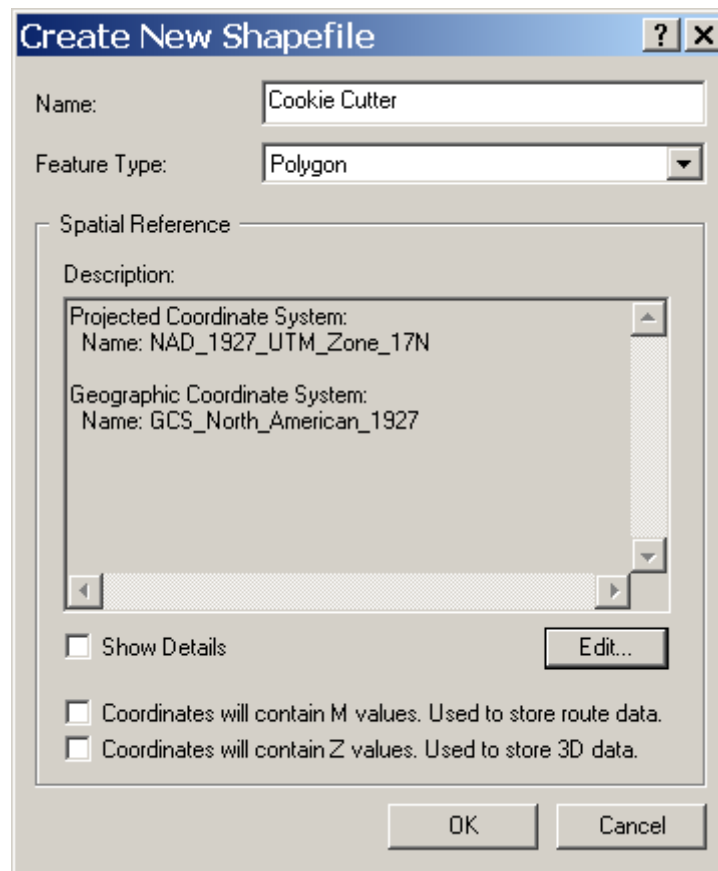

Clipping an ESRI Raster (e.g., DEM or DEM Mosaic)

If ESRI were clever, it would have arranged raster files to be clipped the same way as shapefiles: with the *Geoprocessing* wizard under the *Tools* pull down. Unfortunately, they haven't opted to do so. A completely different procedure must be used based on the *Surface Analyst* tool.

- If necessary, first create a polygon shapefile with the polygon you want to use as the "cookie cutter". Do this by
 - Opening ArcCatalog (either from the Windows Start button or using the  icon from ArcMapper.

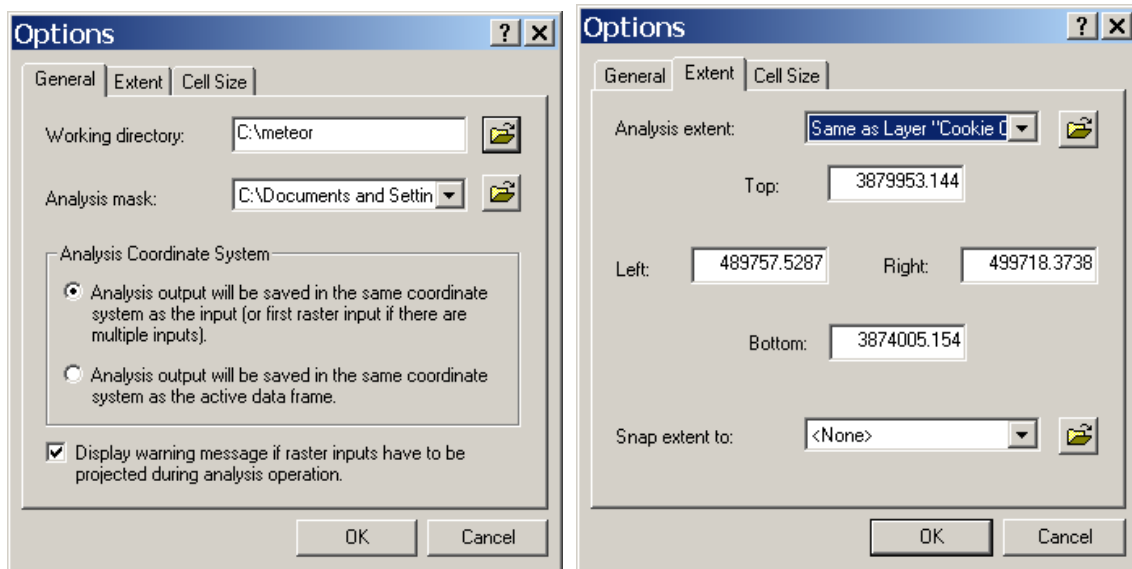

- Navigate to your project folder, right-click and select New>Shapefile...

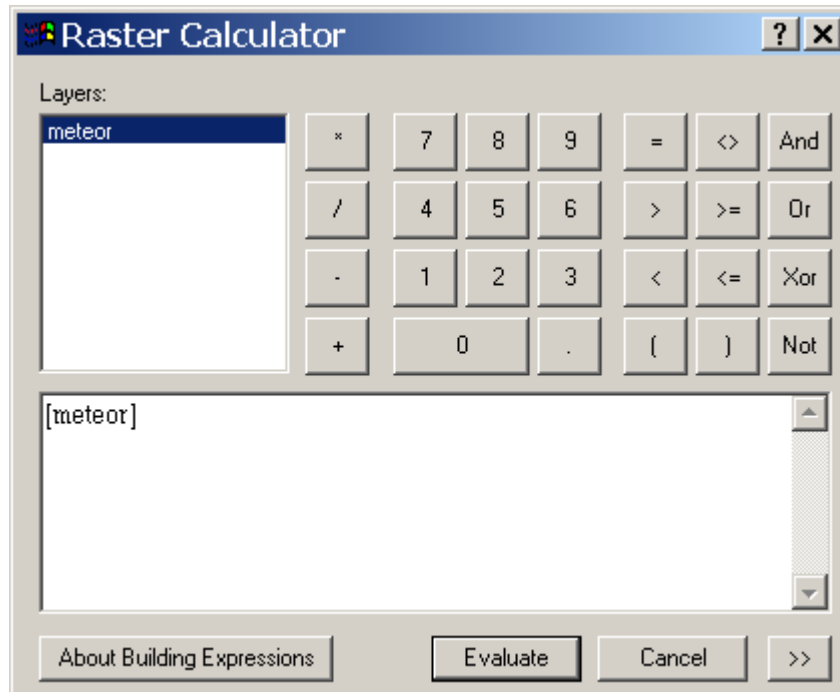

- Fill in the fields (make sure you specify polygon... polyline will not work) and specify the projection.
- Add the cookie cutter shapefile to your ArcMap project folder

- On the editor pull down, select “Start Editing” and select the task as “Create New Feature” and the target as the cookie cutter shapefile.
- 
- Click on the pencil () tool and click the mouse to define the cookie cutter shapefile (double click on last point to complete)
 - Stop editing and save polygon
2. Make certain that the *Spatial Analyst* extension has been selected and the *Spatial Analyst* toolbar is visible.
 3. Pull down the arrow on the *Spatial Analyst* toolbar and select *Options*.

4. Click on the *General* tab (see illustration above). If necessary, change the *Working Directory* to an area on the disk with a lot of space. Use the browser beside the *Analysis Mask* to specify the polygonal shapefile you constructed to clip the raster,
5. Click the *Extent* tab and use the browser to again specify the polygonal shapefile you constructed to clip the raster.
6. Close the dialog box, once again pull down the arrow on the *Spatial Analyst* toolbar, and select *Raster Calculator*.
7. Double click on the name in the upper panel of the dialog box that appears and click *evaluate*.

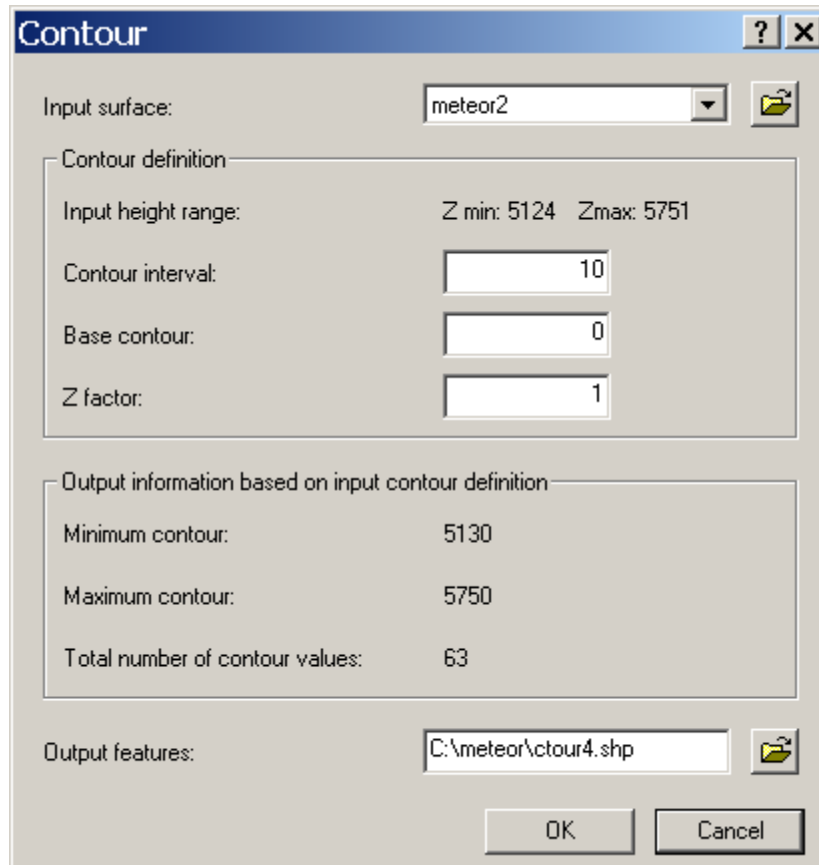

8. The clipped raster image should automatically be added to your ArcMapper project.

Contouring a grid

Last week we converted a TIN to a grid... this week let's convert a grid to a shapefile!

1. From the Spatial Analyst toolbar, select Surface Analysis>Contour

2. Complete dialog as appropriate and press "OK"
3. It does a pretty good job (again, it looks better if you don't look too closely).
