Inhibition of glioma proliferation and migration by magnetic nanoparticle mediated JAM-2 silencing

Lifeng Qi,^{*a} Jing Liu,^a Haiyan Zhu,^a Zhuoquan Li,^a Kun Lu,^a Tian Li^a and Donglu Shi^{*ab}

Brain invasion is a biological hallmark of glioma that leads to its aggressiveness and prognosis. Junctional adhesion molecule-2 (JAM-2) was found to be overexpressed in human glioma. In this study, the effects of JAM-2 silencing mediated by cell-penetrating magnetic nanoparticles were investigated on glioma cell proliferation and migration *in vitro* and *in vivo*. The results showed that the deregulation of JAM-2 in glioma cell lines could cause a dramatic decrease in cell proliferation and migration *in vitro*. The expression level of cytoskeleton remodeling and migration associated protein genes appeared to be a downstream factor of JAM-2. Furthermore, silencing of JAM-2 expression in implanted glioma cells was found to impair *in vivo* tumor growth significantly. These data provide new evidence for the role of JAM-2 in the progression of glioma and show its great potential in human glioma gene therapeutics.

1. Introduction

As a novel member of the Ig superfamily, junctional adhesion molecule-2 (JAM-2) is in a subfamily of junctional adhesion molecules (JAMs) comprising JAM-1 (JAM-A), JAM-2 (JAM-B), and JAM-3 (JAM-C).¹ JAM-2 is specifically enriched in cell–cell contacts at the level of the tight junction,² and is highly expressed in lymphatic and vascular endothelial cells, mostly in high endothelial venules (HEVs).^{3,4} JAM-2 is also expressed in high endothelial venules in human tonsils and in a subset of human leukocytes. JAM-2 plays a central role in regulating transendothelial migration.^{5,6} The counter-ligand of JAM-2 has been identified as JAM-3 and $\alpha_4\beta_1$; therefore, JAM-2 and JAM-3 are known as the protein-interacting pair that is essential for T, NK, and dendritic cell trafficking and inflammation.^{7,8}

JAMs proteins are involved in antitumoral processes. For instance, JAM-A was reported to play an important role in driving breast cancer cell migration *via* the activation of Rap 1 GTPase and β_1 -integrin.⁹ JAM-A's overexpression represents a possibility of a new target for reducing breast cancer metastasis, as it was shown that the abrogation of JAM-A expression can induce breast cancer progression and cell apoptosis.¹⁰ The inactivation of JAM-A was also found to enhance antitumoral immune response, by promoting dendritic cell and T lymphocyte infiltration.¹¹ JAM-C was demonstrated to promote metastasis, by enhancing the adhesion of fibrosarcoma extracellular matrices and mediating lung carcinoma–endothelial cell

interactions.¹² JAM-A and JAM-C were found to be needed for melanoma cell lines transendothelial migration *in vitro*.¹³ JAM-2 was found to be preferentially expressed in the endothelium of arterioles in and around tumors,⁷ and was also found to be aberrantly expressed in glioma. Monoclonal antibodies blocking JAM-2/3 interactions can impair the *in vivo* glioma growth and invasion.¹⁴

RNA interference is one of the most promising technologies for cancer therapeutics, although the development of a safe and effective small interfering RNA (siRNA) delivery system is still challenging. In our recent study, the silencing of JAM-2 by proton-sponge coated quantum dots was found to inhibit glioma migration *in vitro via* NOTCH pathway blockage.¹⁵ For *in vivo* RNAi studies, more biocompatible gene vectors need to be applied. Our recent work reported cell-penetrating magnetic nanoparticles for highly efficient siRNA delivery.¹⁶ To further investigate the biological functionality of JAM-2 during glioma progress, especially for *in vivo* studies, a JAM-2 siRNA delivery, mediated by cell-penetrating magnetic nanoparticles, was performed in this study. The results showed that JAM-2 silencing could inhibit glioma cell proliferation and migration remarkably. The gene expression profiles of JAM-2 siRNA-transfected glioma cells showed the expression level of cytoskeleton organization and migration-associated protein genes deregulated upon activation of the signal transducer. *In vivo* JAM-2 siRNA delivery by cell-penetrating nanoparticles was found to inhibit the growth of implanted glioma cells significantly.

2. Experimental section

Patients' biopsies and cell culture

Biopsies from patients with and without glioma were collected during surgery in the Second Affiliated Hospital of Zhejiang

^aShanghai East Hospital, The Institute for Biomedical Engineering & Nano Science, Tongji University School of Medicine, Shanghai 200120, China. E-mail: leonqi168@163.com

^bThe Materials Science and Engineering Program, Dept. of Mechanical and Materials Engineering, College of Engineering and Applied Science, University of Cincinnati, 45221, Cincinnati, Ohio, USA

University. U251 and U87 glioma cell lines were obtained from the cell bank of the Chinese Academy of Science. Glioma cells with low JAM-2 expression and non-target control cells were cultured in DMEM (Gibco, US) containing 10% FBS (Gibco, US) and $5 \mu\text{g ml}^{-1}$ puromycin (Gibco, US).

Antibodies

Anti-human JAM-2 mouse monoclonal antibody (H00058494-M01) used for the western blotting and IHC was produced by Novus. Anti-human PECAM-1 rabbit monoclonal antibody (ab76533) and anti-human GAPDH mouse monoclonal antibody (ab37187) used as an isotype control were purchased from Abcam. Goat anti-mouse and goat anti-rabbit biotin used for IHC were purchased from Boster Co. LTD. Goat anti-mouse antibody used for western blotting was purchased from Multi-Sciences Biotech Co. LTD (Hangzhou, China).

Western blotting

Glioma cells were lysed in RIPA buffer (50 mM Tris pH 8; 150 mM NaCl; 1% NP40; 0.5% DOC; 0.1% SDS). Twenty micrograms of protein was electrophoresed using SDS-PAGE (12% polyacrylamide gel) and transferred to polyvinylidene difluoride (PVDF) membranes (Millipore, US). PVDF membranes were blocked with 5% non-fat milk/1 \times TBST for 2 h. Primary antibodies (JAM-2 used at a dilution of 1 : 1000, GAPDH used at a dilution of 1 : 2000) were respectively diluted in 5% non-fat milk/1 \times TBST. The PVDF membranes were incubated with the antibody mixtures overnight at 4 °C following the manufacturer's instructions. They were then hybridized with anti-mouse secondary antibody (1 : 1000). Protein bands were visualized using a silver film analysis system.

Immunohistochemistry

The SABC method was used for investigating the JAM-2 protein expression. The immunohistochemistry strictly followed the manufacturer's instructions (Boster, Wuhan, China). Briefly, the tissue slices were incubated in 3% H_2O_2 and blocked with 5% BSA. They were sequentially incubated with the anti-JAM-2 antibody (1 : 200), biotin-conjugated second antibody (1 : 1000), and SABC. For the cryosections, tumor tissues were inflated with OCT before embedding; 7 μm tissue was fixed in methanol (5 min, 220 °C), dried, and then rehydrated in PBS with 0.5% BSA, before processing for immunostaining.

Preparation of cell-penetrating magnetic nanoparticles for siRNA delivery

Cell-penetrating magnetic nanoparticles were prepared according to our recent work.¹⁶ Briefly, PMAL amphipol was used to transfer the hydrophobic magnetic nanoparticles (Nanomics Biopharm, Wuxi, China) to water-soluble nanoparticles. PMAL-modified magnetic nanoparticles were conjugated with protamine peptide by standard EDC-NHS chemistry, and then purified by a dialysis membrane to remove unreacted peptides. The purified and sterilized nanoparticles were stored at 4 °C for direct use. The morphology and particle size of the

cell-penetrating magnetic nanoparticles were characterized by TEM and a zetasizer, respectively. The binding capacity of the cell-penetrating magnetic nanoparticles with siRNA was studied using 0.8% agarose gel electrophoresis.

The JAM-2-targeting sequence of siRNA was CCGGGCTCCTGAATACACATGGTTTCTCGAGAAACCATGTGTATTCAGGAGCTTTTTG. For isotype control, a non-target siRNA (Sigma, US) was also transduced into U251 and U87MG cells. The JAM-2 targeting and control siRNA were labeled with FITC on the sense strand. In the following experiments, U87MG-1 and U251-1 cells were named as U87MG and U251 cells, respectively, transfected with targeted JAM-2 siRNA, while U87MG-2 and U251-2 cells were named as those control cells transfected with scrambled JAM-2 siRNA.

RNA expression analysis

The total RNA of the glioma sample was extracted with RNAiso™ Plus (TaKaRa, Japan). RNA was treated with RNase-free DNase I (TaKaRa, Japan) for 45 min according to the manufacturer's protocols. The final amount of purified RNA was quantified by an ultraviolet spectrophotometer. The total RNA (1 μg) was reverse-transcribed using the SYBR PrimeScript RT-PCR kit II (TaKaRa, Japan) with a random hexamer priming method, according to the manufacturer's recommendations. The following are the sequences of the oligonucleotides used, JAM-2: F = TCTTCTTGGGGTTTTGCAG, R = TACCTGGTGGTCCG CCT, GAPDH: F = TGAGGCCGGTGCTGAGTATGTCGTG, R = TCCTTGGAGGCCATGTAGCCAT.

Cell proliferation and migration assays

Cell proliferation was assayed using a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) staining kit (Sigma-Aldrich, US), according to the manufacturer's protocol. The glioma cells were grown in 96-well plates for six days. The MTT absorbance data was taken at 490 nm by ultraviolet spectrophotometer.

The cell migration assay was performed using transwell chambers (6.5 mm diameter; 8 μm pore size polycarbonate membrane) obtained from Corning. 2×10^5 cells in 0.2 ml FBS-free DMEM were loaded in the upper chamber, whereas in the lower chamber was placed 0.5 ml medium containing 15% FBS. After 48 hours' incubation, the total number of cells that migrated into the lower chamber was counted under an inverted light microscope (Axiovert 25, Carl Zeiss AG, Gottingen, Germany, equipped with an Olympus SC 35 Camera, Volketswil, Switzerland) at $\times 400$.

In vivo tumor growth

In order to study the silencing effects of JAM-2 by cell-penetrating magnetic nanoparticles, U87MG cells stably transfected with an eGFP by lentiviral particles carrying a gene encoding for eGFP plasmid and a puromycin resistance (Sigma-Aldrich, US) were established. At day 0, female inbred BALB/c mice (aged 6–8 weeks) were subcutaneously (s.c.) inoculated into the flank respectively with the U87MG-eGFP cells ($3 \times 10^5/0.1$ ml). After inoculation, the mice were randomly placed into 3 groups (each

Fig. 1 TEM photograph (A) and particle size (B) of cell-penetrating magnetic nanoparticles (CPMN); (C) gel mobility of magnetic nanoparticles (MNP) and CPMN; (D) siRNA binding affinity of CPMN at different molar ratios versus siRNA as 1 : 30 (lane 1), 1 : 20 (lane 2), 1 : 10 (lane 3) and 1 : 5 (lane 4).

Fig. 2 JAM-2 expression in U251 and U87MG glioma cells after JAM-2 targeted siRNA transfection by cell-penetrating magnetic nanoparticles, (A) relatively quantified JAM-2 mRNA expression by RT-PCR in U87MG-1, U251-1, U87MG-2 and U251-2 cells and their agarose gel image (B). U87MG-1 and U251-1 cells were derived, respectively, from U87MG and U251 cells transduced with targeted JAM-2 siRNA, while U87MG-2 and U251-2 cells were derived from those with scrambled JAM-2 siRNA; (C) corresponding western blot results of JAM-2 protein expression in U87MG-1, U87MG-2, U251-1 and U251-2 cells. GAPDH expression was used as an isotype control.

with $n = 5$). The cell-penetrating magnetic nanoparticles, mixed with the JAM-2 targeting and control siRNA respectively, were then injected by intravenous administration through the mice tail vein. *In vivo* transfected mice were scored for tumor growth once every five days, by measuring the diameters of the s.c. tumors and the weight loss with a Vernier caliper. Animals were euthanized 6 weeks post-operatively by transcatheter perfusion using 4% paraformaldehyde. The mouse tumor and lung tissues were harvested, fixed in 4% paraformaldehyde overnight at 4 °C, and then transferred into 30% sucrose. Tissues were paraffin-embedded and sectioned for haematoxylin and eosin staining. At the end of the experiment, tumors were excised to validate the antitumor effects. The mice were maintained under the guidelines established in the guide for the Care and Use of Laboratory Animals (NIH publications, 1986).

Statistical analysis

Results are expressed as mean \pm standard deviation. The significance of difference was calculated by Student's *t* test or Mann Whitney. All experiments were performed in triplicate and repeated at least three times, with comparable results.

3. Results and discussion

JAMs are a family of glycoproteins characterized by two immunoglobulin folds (VH- and C2-type) in the extracellular domain.¹

Fig. 3 Cell proliferation assays on U87MG and U251 glioma cell lines in six days by MTT method. U87MG-1 and U251-1 cells were derived, respectively, from U87MG and U251 cells transduced with targeted JAM-2 siRNA, while U87MG-2 and U251-2 cells were derived from those with scrambled JAM-2 siRNA, the proliferation of U87MG and U251 cells with JAM-2 low expression is highly inhibited during six culture days. Fluorescent image (B) and corresponding bright field image (C) of intracellular JAM-2 FITC labeled siRNA delivery via CPMN into U87MG cells.

As one subfamily of JAMs, JAM-2 has a more restricted distribution, mostly in high endothelia venules (HEVs), which are portals of entry into lymphatic tissues for lymphocytes responding to processed antigens.⁴ The overexpression of JAM-2 has been observed in glioblastoma within the normal brain.¹⁴ In a recent study of ours, the silencing of JAM-2 in glioma cells was found to inhibit glioma migration significantly, by blockage of the NOTCH1 pathway.¹⁵ The *in vitro* and *in vivo* study of JAM-2 in glioma was carried out to investigate the underlying signal transducer events, and the effects of stable JAM-2 siRNA transfection in glioma cells on cell growth, invasion, mRNA expression profile, and *in vivo* tumor growth.

In order to study the function of JAM-2 in glioma cells, U251 and U87MG cells were transfected with JAM-2 targeted siRNA and a scrambled siRNA, respectively. The prepared cell-penetrating magnetic nanoparticles were characterized by TEM image and particle size. The binding capacity of the cell-penetrating magnetic nanoparticles with siRNA was examined by 0.8% agarose electrophoresis. As shown in Fig. 1, the cell-

penetrating magnetic nanoparticles exhibited uniform morphology, and had a particle size of about 15 nm. The gel mobility of the cell-penetrating magnetic nanoparticles was greatly enhanced compared with the control magnetic nanoparticles without peptide modification. Cell-penetrating magnetic nanoparticles demonstrated high affinity with siRNA molecules up to higher than 1 : 20 molar ratio.

RT-PCR and western blot were used to confirm the knock-down efficiency of the siRNA transfection. As shown in Fig. 2, compared with the control cells without any treatment and with the non-targeting siRNA sequence delivery, JAM-2 expression is down-regulated to 30% at both the mRNA and protein levels in U251-1 cells, while almost being completely silenced in U87MG-1 cells upon JAM-2 siRNA delivery.

Cell proliferation assays were performed to determine the effects of JAM-2 knockdown on glioma cells growth. Glioma cells were transfected with JAM-2 target and control siRNA respectively. As shown in Fig. 3, significant difference is observed on cell growth among the three groups from the 72 h

Table 1 Genes differentially expressed in JAM-2 knockdown cells (U87MG-1, U251-1) compared with U87MG-2 and U251-2 cells

Gene symbol	Gene ontology biological process	Gene ontology molecular function	Fold (U87MG-1)	Fold (U251-1)	Reg.

culture. On the sixth day of culture, the glioma cell growth of U87MG-1 and U251-1 cells with low JAM-2 expression was retarded about 95% and 86%, respectively, compared with the non-targeted control cells (Fig. 3A). Fluorescence microscope imaging showed the intracellular JAM-2 siRNA delivery by cell-penetrating magnetic nanoparticles, as shown in Fig. 3B.

Cell-penetrating magnetic nanoparticles for siRNA delivery have been developed by our group recently, where the magnetic nanoparticles were modified with protamine, a kind of arginine-rich cell penetrating peptide (CPPs).¹⁶ In recent years, arginine-rich CPPs, that are relatively short cationic and/or amphipathic peptides, have received significant attention as efficient cellular gene delivery vectors, due to their intrinsic ability to enter cells and mediate the uptake of plasmid DNA (pDNA), small interfering RNA (siRNAs), and nanoparticulate pharmaceutical carriers.^{17–19} L-Arginine-modified polymers have been demonstrated as efficient non-viral gene delivery vectors with little cytotoxicity.²⁰ The enhanced siRNA intracellular delivery by cell-penetrating magnetic nanoparticles is attributed to their excellent endosomal escape of nanoparticles–siRNA complexes due to the CPPs' modification.

JAM-2 was mostly overexpressed in U251 cells, as reported in our previous study.¹⁵ Using the RNA interference (RNAi) technique, we obtained U251-1 and U87MG-1 cells with reduced

levels of JAM-2 protein compared with the U251-2 and U87MG-2 cells transfected with scrambled JAM-2 siRNA. These two kinds of transfected cell lines were then used for the comparative gene expression analysis. In the JAM-2 silencing of U251-1 and U87MG-1 cells, respectively, with an 18.5-fold and 14.6-fold JAM-2 deregulation as shown by the affymetrix microarray analysis, 14 genes down-regulated and 5 genes up-regulated (Table 1) were founded. Among the differentially expressed genes, several are known to be involved in cytoskeleton reorganization, cell migration, and invasion. The actin binding associated genes, such as SPTBN5, TAGLN, DIXDC1, APIRE2, BAIAP2L1, and DMD, were deregulated significantly after the JAM-2 knockdown. Among them, DMD (differentially methylated domains) was the most differentially expressed gene, with a 5.88-fold and 6.57-fold decrease, respectively, in U251-1 and U87MG-1 cells. The structural molecule activity related genes, such as KRT6B, PLP1, AP4E1, KRT25 and TTC23, were also deregulated and correlated with the JAM-2 deregulation. The cytoskeleton reorganization associated genes were the downstream factor of JAM-2. On the other hand, the signal transducer activities of glioma cells, with a low JAM-2 expression, were activated to inhibit the tumor cell growth and maintenance. TFG, RGS7, GNG2, and TICAM1 were up-regulated significantly.

Fig. 4 Cell migration assays with transwells. After 48 hours' incubation, the total number of cells that have migrated into the lower chamber is counted (A), and the corresponding photos are taken under a light microscope at $\times 400$, (B) U87MG cells with target JAM-2 delivery; (C) U87MG-2 cells with control JAM-2 siRNA delivery; (D) U251-1 cells with target JAM-2 delivery; (E) U251-2 cells with control JAM-2 siRNA delivery.

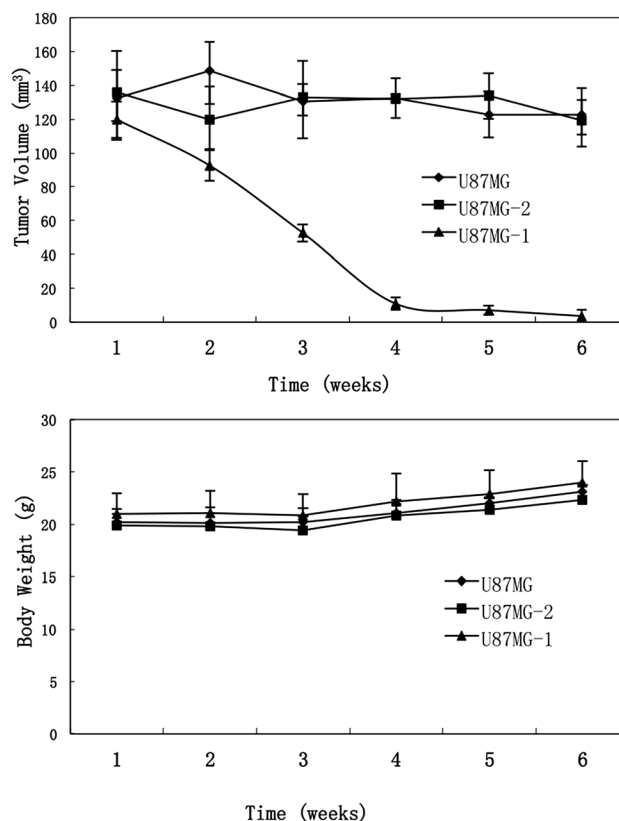

Fig. 5 JAM-2 knockdown in U87MG cells inhibits *in vivo* glioma growth, the figures refer to the tumor volume analysis, and the body weight increase during the 42 days mice growth, post tumor cell implantation, and the values obtained from the five mice treated with control U87MG cells and U87MG-1 cells after JAM-2 siRNA delivery and U87MG-2 cells after scrambled JAM-2 siRNA delivery.

Fig. 6 The macroscopic appearance of excised tumor and nude mice from different groups under *in vivo* animal fluorescence imaging instrument (A), and representative pictures of haematoxylin/eosin staining of tumor sections used for the quantification of JAM-2, PECAM-1 expression, and cell morphology observation (B). The tumor tissues and sections were obtained from five mice treated with control U87MG cells and U87MG-1 cells after JAM-2 siRNA delivery and U87MG-2 cells after scrambled JAM-2 siRNA delivery.

TFG (TRR-fused gene) has been identified as a novel member of the NF-kappaB pathway.²¹ It was found in this study to be mostly up-regulated, with an 8.4-fold and 11.2-fold increase, respectively, in U251-1 and U87MG-1 cells. RGS7 and GNG2 were the G-protein coupled receptor protein signaling pathways. The TICAM1 gene expression indicated macrophage activation during the immune response. PVR, a receptor activity related gene, which was implicated in glioma invasion,²² was deregulated with the JAM-2 expression in glioma cells.

The correlation between the expression of JAM-2 and the genes was investigated in terms of the cytoskeleton dynamics and cell motility. *In vitro* cell migration assays were performed by comparing the counterparts of U251-1 vs. U251-2 cells, and the U87MG-1 vs. U87MG-2 cells. Cell migration was studied by the use of transwells chambers. As shown in Fig. 4, after JAM-2 knockdown, glioma cell migration is inhibited significantly compared with the control cells without any treatment. An average reduction of 87% and 82% ($p < 0.01$) in cell migration was observed, respectively, in U87MG-1 and U251-1 cells with low JAM-2 expression.

The effects of JAM-2 knockdown on a subcutaneous U87MG xenograft model was studied by U87MG cells implanted mice. Cell-penetrating magnetic nanoparticles complexed with JAM-2 siRNA, and scrambled siRNA were intravenous administrated, respectively, followed by 6 weeks' growth. The tumor size

diameters were measured every five days to determine the effects on tumor growth. It was found that JAM-2 knockdown inhibited the xenograft growth by up to 95%, compared with the scrambled siRNA control, with no significant body weight increase (Fig. 5). Upon dissection, the tumor size of the control group was found to be much larger than those of the JAM-2 siRNA targeted group. Only two in five mice from the JAM-2 silencing group showed macroscopical tumor tissues, with one displaying GFP expression, indicating the presence of tumor cells (Fig. 6A). Histologically, scrambled siRNA tumors exhibited large, distinct areas of tumor formation (Fig. 6B), whereas the JAM-2 siRNA expressing xenografts were much smaller and exhibited tumor necrosis morphology, and showed decreased JAM-2 and PECAM-1 expression. These data are clear evidence for JAM-2 expression being required for the *in vivo* growth of glioma cells.

Gene profile experiments were carried out on the mRNA profile of U251-1 and U87MG-1 cells after JAM-2 silencing. The results showed that deregulation of the cytoskeleton reorganization associated genes were correlated with JAM-2 silencing. The signal transducer activities of glioma cells, with low JAM-2 expression, are activated to inhibit tumor cell growth and maintenance. DMD (differentially methylated domains) is the most differentially expressed gene in JAM-2 suppressed cells. DMD located between IGF2 and H19 on human chromosome 11

has been found to regulate insulin-like growth factor 2 (IGF2) gene imprinting.²³ The loss of IGF2 imprinting is responsible for the tumor growth inhibition *in vitro* and *in vivo*.²⁴ KRT6B and PLP1 are significantly deregulated in JAM-2 low expression glioma cells. KRT6B is known as a gene with cell growth and maintenance activity.²⁵ PLP1, a signature gene specific to oligodendrocytes, is always expressed in glioblastoma with high oligodendroglioma.²⁶ The deregulation of PLP1 showed the decreased malignant grade of glioma cells with low JAM-2 expression. PVR, associated with interspecies interaction between organisms, is regarded as a functional link with glioma invasion.²⁷ Deregulated PVR expression in glioma cells with low JAM-2 expression indicates a reduced cell invasion capacity.

RGS7 and GNG2 are G-protein coupled receptor protein signaling pathway related genes, and they are up-regulated greatly upon the deregulation of JAM-2. TFG (TRR-fused gene) is a novel member of the NF-kappaB pathway. TFG protein has been found to enhance the tumor necrosis factor (TNF)- α , TANK, and TNF receptor-associated TRAF2 and TRAF6 by inducing the NF-kappaB activity.²⁸ On the other hand, (TNF)- α is known to prevent the proteasome-dependent degradation of RGS7, a regulator of G-protein signaling.²⁹ (TNF)- α has also been reported to induce NF- κ B activation in GBM.³⁰ GNG2, a G-protein signaling pathway associated gene, is shown to be up-regulated in glioma cells with JAM-2 silencing. The increased protein expression level of GNG2 alone can inhibit the proliferation of malignant tumor cells *in vitro* and *in vivo*. These data suggests that JAM-2 could be a novel molecular target for malignant tumor therapy.³¹

4. Conclusion

In summary, our experimental results have shown significant inhibition of cell growth, cell migration, and invasion by deregulated JAM-2 expression in glioma cells. The *in vivo* growth of implanted glioma was also inhibited significantly by JAM-2 silencing, mediated by cell-penetrating magnetic nanoparticles. Cytoskeleton reorganization associated genes are deregulated in correlation to the JAM-2 silencing, disrupting cell maintenance and invasion. Insulin-like growth factor 2 gene (IGF2) imprinting has been successfully suppressed. The TFG and TNF-alpha mediated NF-kappaB pathway and G-protein signaling have been activated to inhibit glioma proliferation.
